Database Backup

how to backup correctly

To backup a database you can use the mostly supported tool phpMyAdmin.
Please ask your provider for the path to this program.

The following screenshots may differ, depending on the version of phpMyAdmin. The way to use the program stays the same.

click to enlarge

Upon opening phpMyAdmin, there is a startpage on the screen. Click on the databasename to get to the second step. The databasename is marked red in the pictures.

To create a complete backup of your database follow these steps.

On the right side locate the field **Export** Choose **Select All** or you choose only the phpWCMS tables. The

easiest way to do that is to first click on phpWCMS while holding down the shift key on the keyboard. While pushing down the shift key, drag the arrow over the entire table until the entire table is highlighted, making sure that all phpWCMS are marked.

Then choose the **SQL options** on the right.

Add DROP TABLE, this will overwrite all phpWCMS tables

There should be a hook at **data**.

Then choose **compression gzip**.
Now click on **OK** and a *zip-file will be created which will include the database backup. back to:
